GOVERNMENT INTEREST

[0001] This invention was made with government support under grant CA 78039 awarded by the National Institutes of Health. The government has certain rights in this invention.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0002] The present application claims the benefit of U.S. Provisional Patent Application Serial No. 60/408,503, filed September 6, 2002 and U.S. Provisional Patent Application Serial No. 60/437,736 filed January 2, 2003, the disclosures of which are incorporated herein by reference.

BACKGROUND OF THE INVENTION

[0003] The present invention relates to analogs of discodermolide and dictyostatin-1, intermediates for the synthesis of such analogs and methods of synthesis of such intermediates and analogs.

[0004] References set forth herein may facilitate understanding of the present invention or the background of the present invention. Inclusion of a reference herein, however, is not intended to and does not constitute an admission that the reference is available as prior art with respect to the present invention.

[0005] The discovery and development of new chemotherapeutic agents for the treatment of cancer is currently of high importance. Some of the best currently available chemotherapeutic agents are natural products or natural product analogs. For example, Taxol (paclitaxel) is a natural product that is currently being used to treat patients with breast and ovarian cancer among others. A number of analogs of Taxol, including Taxotere (docetaxel), are also powerful anticancer agents.

[0006] Recently, the natural product (+)-discodermolide and its analogs have shown great promise as anticancer agents. Discodermolide has been shown to have a mechanism of action similar to Taxol but it is active against Taxol-resistant cell lines and it is more water soluble than Taxol. Accordingly, it may have a different and/or broader spectrum of action than Taxol and be easier to formulate and administer. Like Taxol, discodermolide is difficult

to synthesize. Some syntheses of discodermolide are described in the following papers: Nerenberg, J. B.; Hung, D. T.; Somers, P. K.; Schreiber, S. L. Total synthesis of the immunosuppressive agent (-)- discodermolide. *J. Am. Chem. Soc.* 1993, 115, 12621-12622; Smith, A. B., III; Qiu, Y.; Jones, D. R.; Kobayashi, K. Total Synthesis of (-)- Discodermolide. *J. Am. Chem. Soc.* 1995, 117, 12011-12012; Marshall, J. A.; Johns, B. A. Total synthesis of (+)-discodermolide. *J. Org. (-)-taxol

(+)discodermolide

[0007] Analogs of discodermolide have also been made and tested for activity. For example, see the above references and Paterson, I.; Florence, G. J.; Gerlach, K.; Scott, J. P.; Sereinig, N. A practical synthesis of (+)-discodermolide and analogues: Fragment union by complex aldol reactions. *J. Am. Chem. Soc.* 2001, 123, 9535-9544; Martello, L. A.; LaMarche, M. J.; He, L.; Beauchamp, T. J.; Smith, A. B. et al. The relationship between taxol and (+)-discodermolide: synthetic analogs and modeling studies. *Chemistry Biol.* 2001, 8, 843-855; Harried, S. S.; Yang, G.; Strawn, M. A.; Myles, D. C. Total Synthesis of (-)- Discodermolide: An Application of a Chelation-Controlled Alkylation Reaction. *J. Org. Chem.* 1997, 62, 6098-6099; Paterson, I.; Florence, G. J. Synthesis of (+)-discodermolide and analogues by control of asymmetric induction in aldol reactions of gamma-chiral (Z)-enals. *Tetrahedron Lett.* 2000, 41, 6935-6939.

[0008] Unlike Taxol, discodermolide is not readily available in large quantities from natural sources. Accordingly, assuring a sufficient supply of discodermolide is problematic. Simplified analogs that retain high anti-cancer activity but are easier to make are in urgent need.

[0009] Very recently, an unusual macrolactone natural product dictyostatin 1 has been isolated from two different sponges and a partial structure has been assigned as shown below. See Pettit, G. R.; Cichacz, Z. A. Isolation and structure of dictyostatin 1. In US 5,430,053; 1995; Pettit, G. R.; Cichacz, Z. A.; Gao, F.; Boyd, M. R.; Schmidt, J. M. Isolation and structure of the cancer cell growth inhibitor dictyostatin 1. *J. Chem. Soc., Chem. Commun.* 1994, 1111-1112. The configurations at C16 and C19 have not yet been assigned in the natural product and the absolute configuration is not known. Dictyostatin shows extremely high potencies against an array of cancer cell lines.

dictyostatin 1

absolute configuration unknown, configurations at C16 and C19 unknown

[0010] Recently, dictyostatin has also been shown to stabilize microtubules, like discodermolide and Taxol. See Wright, A. E.; Cummins, J. L.; Pomponi, S. A.; Longley, R. E.; Isbrucker, R. A. Dictyostatin compounds for stabilization of microtubules. In *PCT Int. Appl.*; WO62239, 2001. Accordingly, dictyostatin 1 and its analogs show great promise as new anticancer agents. There is an urgent need for a synthetic route to make dictyostatin 1 and its analogs in order to fully assign the structure of dictyostatin 1, to produce analogs to study the structure/activity relationship and to identify and produce the best possible drugs in this family.

[0011] The inventors of the present invention, as one aspect of the present invention, herein set forth a number of analogs of discodermolide, as well as methods and intermediates

for the synthesis thereof. The inventors of the present invention, as another aspect of the present invention, herein set forth a family of both closed and open analogs of dictyostatin 1 with methods and intermediates for the synthesis of this family.

## DETAILED DESCRIPTION OF THE INVENTION

[0068] **Synthesis of Simplified Analogs of Discodermolide:** The inventors of the present invention hypothesized that active analogs of discodermolide would result after removal of the C14 and C16 methyl groups and the C7 hydroxy group. These deletions greatly simplify the synthesis by allowing the two cis-disubstituted alkenes of analogs 1 and 2 to be made by Wittig-type reactions. A family of simple analogs 1 were shown to have moderate activity. However, by incorporating a lactone in place of the simple ester side chains of 1, the inventors of the present invention have discovered anti-cancer agents of increased activity that are still significantly simpler to make than discodermolide.

[0069] The syntheses of two representative isomeric aldehydes 9a and 9b for incorporation of the left part of these molecules are shown in Figures 1 and 2. The synthesis of the left display bearing the configuration of (+)-discodermolide started with the commercially available methacrolein 3 (Figure 1). Reaction of 3 with the boron enolate of Evans oxazolidinone 4 gave the corresponding alcohol, which was silylated to give compound 5 in 90% yield. Lactonization followed by the introduction of allyl group was performed by the previously reported method to give 6 in good yield. See Day, B. W.; Kangani, C. O.; Avor, K. S. Convenient syntheses of (2R,3S,4R)-3-(tert-butyldimethylsilyloxy)-2,4-dimethyl-5-oxopentanoic acid methoxymethyl-amide from methacrolein. Preparation of C1-C7 and C17-C24 fragments of (+)-discodermolide. *Tetrahedron Asymmetry* 2002, 13, 1161-1165. Lactone opening, oxidation and allylation gave 7. Conversion to the methyl acetal was accomplished by DIBAL (diisobutylaluminum hydride) reduction to the corresponding lactol followed by treatment with camphorsulfonic acid (CSA) in methanol to give a desilylated intermediate, which was protected with methoxymethyl chloride (MOMCl) to give a mixture of anomers 8 ( $\beta:\alpha = 1:1$ ). These were separable by silica gel flash chromatography. The final left fragment 9a was obtained by hydroboration of the  $\alpha$ -anomer 8 with  $\text{BH}_3\text{-DMS}$  (borane-dimethylsulfide) followed by oxidation with  $\text{SO}_3\text{-pyridine}$ .

[0070] The synthesis of the C4-epi lactone left display 9b started from 1,4-butanediol (Figure 2). Monoprotection with PMB bromide (PMB is *p*-methoxybenzyl) was performed with NaH in DMF. After oxidation, reaction of the crude aldehyde 10 with the boron enolate

of Evans oxazolidinone 4 gave the corresponding *syn*-alcohol, which was silylated to give compound 11 in 90% yield. Lithium borohydride reduction followed by oxidation gave the aldehyde 12. A second *syn*-aldol addition was performed with same Evans oxazolidinone 4 to give the corresponding alcohol, which was protected with MOM chloride to give compound 13. Desilylation of 13 with HF gave the cyclized product 14 in high yield. Conversion to the methyl acetal was easily accomplished by DIBAL reduction to the corresponding lactol followed by treatment with PPTS (pyridinium *p*-toluene sulfonate) in methanol to give 15 as a 2.5:1 ( $\alpha$ : $\beta$ ) mixture of anomers from which the major anomer ( $\alpha$ ) was isolated by silica gel flash chromatography. The final left fragment 9b was obtained by hydrogenolysis of the PMB protecting group followed by Dess-Martin oxidation.

[0071] These synthetic routes are flexible and substantially any stereoisomer of the lactone 9 can be made with the appropriate chiral auxiliary and reaction conditions.

[0072] Center intermediate 21 was prepared as shown in Figure 3. Oxazolidinone 18 was prepared from (*S*)-3-hydroxy-2-methylpropionic methyl ester 16 by the known procedure for the preparation of *ent*-18. See Clark, D. L.; Heathcock, C. H. Studies on the alkylation of chiral enolates: application toward the total synthesis of discodermolide. *J. Org. Chem.* 1993, 58 5878-5879. Reduction of 18 with lithium borohydride gave the diol, which was protected by anisaldehyde dimethyl acetal 19 to give the acetal 20. Deprotection of the primary TBS group with tetrabutylammonium fluoride (TBAF), iodination, and treatment with triphenylphosphine afforded the phosphonium salt 21 in 72% yield. Phosphonium salts 22 and 23 were also used for Wittig olefination, but the results were unsatisfactory. Smith also encountered difficulties with related Wittig reagents in discodermolide synthesis. See: Smith, A. B.; Beauchamp, T. J.; LaMarche, M. J.; Kaufman, M. D.; Qiu, Y. P. et al. Evolution of a gram-scale synthesis of (+)-discodermolide. *J. Am. Chem. Soc.* 2000, 122, 8654-8664. These difficulties may result, at least in part, from the hygroscopic nature of the phosphonium salts. In contrast, compound 21 is a white, non-hygroscopic solid and its Wittig reactions were reliable even though no special care was taken with its storage (for example, salt 21 was useful for reactions even after it was stored at room temperature for several months).

[0073] As shown in Figure 4, the construction of the right fragment 34 featured aldol reactions. *Syn*-Aldol reaction of aldehyde 24 with 4 provided 25, which was reduced to a diol and protected with anisaldehyde dimethyl acetal 19 to give 26. Selective opening of the benzylidene ring of 26 with DIBAL gave a primary alcohol, which was oxidized to aldehyde 27. The subsequent *anti*-aldol condensation using Heathcock's aldol reaction with

dimethylphenyl propionate **28** furnished compound **29** as the major product in 73% yield. See Heathcock, C. H.; Pirrung, M. C.; Montgomery, S. H.; Lampe, J. Acyclic stereoselection-13; Aryl esters: reagents for threo-aldolization. *Tetrahedron* 1981, 37, 4087-4095. The relative configuration of intermediate **29** was confirmed by  $^{13}\text{C}$  and  $^1\text{H}$  NMR analyses of the corresponding acetonide **34**. Silylation of the newly formed hydroxyl group of **29**, reduction of the aryl ester with DIBAL and Dess-Martin oxidation of the resultant primary alcohol afforded aldehyde **30**. The Z-diene moiety was introduced by a two-step procedure developed by Paterson and coworkers using a Nozaki-Hiyama reaction. See Paterson, I.; Schlapbach, A. Studies towards the total synthesis of the marine-derived immunosuppressant discodermolide: stereoselective synthesis of a C9-C24 subunit. *Synlett.* 1995, 498-500. Addition of the aldehyde **30** and allyl bromide **31** to a suspension of  $\text{CrCl}_2$  in THF produced an intermediate  $\beta$ -hydroxy silane (not shown), which upon treatment with NaH underwent *syn* elimination to generate the required Z-diene **32**. Selective deprotection of the primary TBS group, iodination, and then treatment with triphenylphosphine gave the phosphonium salt **33** in good yield.

[0074] The first Wittig reaction of **9a** with **21** provided **35** (see Figure 5). DIBAL reductive cleavage of the acetal followed by Dess-Martin oxidation gave aldehyde **37**. Likewise, aldehyde **38** was made from **9b** via **36**. The second Wittig olefination was accomplished with **38** as an example and phosphonium salt **33** (Figure 5). Tetrabutylammonium fluoride deprotection followed by carbamoylation using Kočovsky's method (See Kočovsky, P. Carbamates: a method of synthesis and some synthetic applications. *Tetrahedron Lett.* 1986, 27 5521-5524) afforded the C19 carbamate-containing compound **39**. The lactone was built from the methyl acetal in the left fragment by using aqueous 60% acetic acid in THF followed by Dess-Martin oxidation. Deprotected analog **40** containing a free C3 hydroxy group on the lactone was obtained by the removal of MOM group with 4N HCl followed by removal of the PMB protecting groups with DDQ oxidation. Two additional example compounds, **41** and **42**, were prepared from the intermediate **39** by using appropriate conditions. All three of these analogs exhibited significant activity, as shown in Figures 6A-D and Table 1. Surprisingly, the C3-MOM-protected analogs **41** and **42** showed better microtubule hypernucleation activities than the analog **40** with a free C3-hydroxy group. As can be seen in Figure 6A, discodermolide is superior to paclitaxel (taxol) in that it causes equivalent microtubule assembly at both lower concentrations and temperatures (the increase in absorbance caused by discodermolide occurs at a time point

earlier than that caused by paclitaxel). Additionally, the polymer induced to form by discodermolide is more resistant to cold-induced disassembly than is the paclitaxel-induced polymer. Both analogs 41 (Figure 6C) and 42 (Figure 6D) showed these more rapid polymer-inducing and cold-resistant properties, albeit at somewhat lower potencies (for example, higher concentrations of the analogs were necessary for these effects to be detected) than discodermolide. MOM ether lactone 41 was the most potent among these analogs.

[0075] Table 1 shows microtubule stabilizing, antiproliferative, and paclitaxel-displacing properties of 40-42. Again, the lactone, MOM ether 41 was more potent than the lactol 42 or free hydroxy 40 relatives. The cellular activity of 41 was good, showing a submicromolar 50% growth inhibitory (GI<sub>50</sub>) concentration. This compound also showed considerable affinity for the paclitaxel binding site on tubulin. A 2-fold molar excess of 41 displaced [<sup>3</sup>H]paclitaxel from microtubules better than paclitaxel and at almost the same potency as discodermolide.

[0076] Macrocycle 43 is a representative example of a dictyostatin analog with an alkyl chain bridging the lactone carbonyl group and the C10/C11 alkene and with two Z-double bonds in the macrocycle. It can also be considered as a macrocyclic analog of discodermolide. This can be synthesized convergently from three components—33, 21 and 44—via sequential Wittig couplings and a macrocyclization (Figure 7). This design allows

the synthesis of substantially any stereoisomer by employing the desired isomer of the relevant precursor—21 or 33.

[0077] Fragment 45 was synthesized from 1,10-decanediol (not shown) by mono-TBS protection (NaH/TBSCl, 42%) followed by Dess-Martin oxidation (80%). Fragment 21 was prepared as shown in Figure 3. Fragment 33 was prepared as shown in Figure 4.

[0078] The coupling of the three fragments is summarized in Figure 8. Generation of the ylide from phosphonium salt 21 and NaHDMS followed by addition of aldehyde 44 gave the Wittig product in good yield (75%) provided that the reaction was conducted at high concentration (1M in 21). The formation of the Z-alkene was confirmed by the 10 Hz coupling constant between the vinyl protons. Selective opening of the PMB acetal was accomplished by addition of 3 equiv of DIBAL to give a primary alcohol. This was oxidized to an aldehyde under Dess-Martin conditions. Wittig conditions similar to those above were then deployed to prepare 45 from this aldehyde and phosphonium salt 33.

[0079] Selective deprotection of 45 was achieved using HF-pyridine and the resulting primary alcohol was oxidized to acid 46. The other TBS group was then removed with TBAF. Using the Yamaguchi protocol, the macrolactone ring was then constructed. PMB deprotection using DDQ provided target product 43, whose protons and carbons were assigned by COSY and HMQC NMR experiments. The location of the macrolactone ring was confirmed by HMBC NMR experiments.

[0080] Acyclic compounds 47, 48 and 49 were readily made from appropriate synthetic intermediates (45 or 46) in reasonable yields (Figure 9).

[0081] These analogs were tested for antiproliferative activity *in vitro* against two human cancer cell lines (Table 2). Macrolactone 43 and non-cyclized alcohol 47 and ester 48 exhibited similar 50% growth inhibitory concentrations, in the 15-30  $\mu$ M range. Carboxylic acid 49 was inactive (>50  $\mu$ M) possibly due to poor cell membrane penetration. The modest activity of these compounds is encouraging given the simplicity and flexibility of their lower chain.

[0082] We therefore decided to introduce the more complex bottom part of dictyostatin-1 lacking only the C9'-OH group. The synthesis of a lower fragment more closely related to dictyostatin is shown in Figure 10. Synthesis of the needed aldehyde 51 (Figure 10) started from the intermediate 25, which was reduced to an alcohol with LiBH<sub>4</sub>, followed by PMB acetal protection as in Figure 4. Selective acetal opening produced alcohol 50, which was subjected to Dess-Martin oxidation to give aldehyde 27 (see Figure 4).

Wittig-Horner reaction, and removal of the TBS group with HF-pyridine gave a primary alcohol, which was oxidized to aldehyde 51.

[0083] Center part Wittig salt 21 (Figure 3) was reacted with aldehyde 51 to give the (Z)-olefin (Figure 11). This was followed by selective PMP acetal opening with NaCNBH<sub>3</sub>-TMSCl to yield a primary alcohol. The aldehyde obtained after Dess-Martin oxidation was again subjected to Wittig reaction with 33 to generate 52. Ester 52 was reduced to the alcohol with DIBAL, followed by Dess-Martin oxidation and application of the Still (Z)-variant of the Wittig reaction to afford (E,Z) doubly unsaturated ester 53. Selective removal of the TBS groups was accomplished by exposure to 3N HCl-MeOH in THF (1:1). The resulting ester was hydrolyzed by using 1N KOH in refluxing in EtOH. Finally, the Yamaguchi lactonization protocol followed by DDQ deprotection gave macrolactone 54, whose structure was confirmed by HMBC and other NMR experiments. No isomerization of either of the dienes or the isolated *cis*-alkenes was detected.

[0084] Compound 54 proved to be quite potent in terms of antiproliferative activity against human carcinoma cells (Table 2) showing a 50% growth inhibitory concentration against breast and ovarian cancer cells of about 1  $\mu$ M. Furthermore compound 54 displaced [<sup>3</sup>H]paclitaxel stoichiometrically bound to microtubules at about 1/3rd the potency of discodermolide.

[0085] A second representative general strategy for the synthesis of stereoisomers and close analogs of dictyostatin is shown in Figure 12. Again the molecule is dissected such that

every stereocenter can be controlled and modified either by starting with an appropriate precursor or through an asymmetric reaction allowing access to both possible isomers.

[0086] Figure 13 summarizes the synthesis of the bottom fragment. (S)-Diethyl maleate was reduced and the resulting diol was converted to acetonide 55. Reduction to the aldehyde and standard Evans aldol reaction gave 56. Reduction of this to the aldehyde and Wittig-Horner Emmons reaction gave 57. Removal of the acetonide and silylation gave 58, which was mono-desilylated to 59 and oxidized to aldehyde 60.

[0087] Coupling of the bottom fragment with the center fragment and elaboration are shown in Figure 14. Wittig reaction of 21 (Figure 3) and 60 proceeded smoothly to form 61, which was hydrolyzed and reduced to give 62. After tritylation to 63, DIBAL reduction gave 64. Oxidation and Wittig-Horner reaction produced 65, which was reduced to give 66 and hydrolyzed to acid 67. Activation of 67 as the mixed anhydride preceded conversion to the oxazolidinone 68.

[0088] Introduction of the C16 stereocenter and introduction of the top fragment are shown in Figure 15. Evans asymmetric alkylation to 69 followed by removal of the chiral auxiliary by reduction gave 70. Separately, reagent 71 was made from the Evans oxazolidinone by displacement with  $\text{LiCH}_2\text{P}(\text{O})(\text{OMe})_2$ . Dess-Martin oxidation and Horner-Emmons olefination with 71 then gave 72, which was reduced with  $\text{NiCl}_2/\text{NaBH}_4$  to 73. Now reduction with sodium borohydride gave a 2.8/1 mixture of stereoisomers, which could be separated and converted to the final products independently. Silylation to 75 followed by DIBAL reduction gave 76, which was converted to diene 77 as described above. Detritylation then gave 78.

[0089] Completion of the synthesis is shown in Figure 16. Dess-Martin oxidation and Still-Gennari olefination gave 79 which was deprotected with DDQ to 80. Saponification then gave the hydroxy acid 81 ready for macrocyclization. Treatment of 81 under the Yamaguchi protocol gave 82, which was finally deprotected to give the target product 83, an isomer of dictyostatin 1 called dictyostatin 5.

[0090] Representative methods to make analogs of the terminal diene fragment are shown in Figure 17. Alkene 84 was ozonized to give the aldehyde, which was subjected to a Wittig reaction to give analogs like 85. Alternatively, 84 can be converted to the Z-vinyl iodide 86, which can in turn be coupled with organometallic reagents like phenyl zinc iodide to give 87. This combination of olefination and organometallic and related coupling methods allows access to a wide variety of groups in this position.

[0091] The versatility of the synthesis is illustrated by the preparations of representative additional fragments that can be used to make dictyostatin, its isomers and its analogs. Figure 18 summarizes the synthesis of a fully elaborated bottom fragment 92. Acetal 88, readily prepared from (D)-malic acid, was silylated with t-butyldiphenylsilyl chloride (TBDPSCI). Reductive cleavage of the acetal with DIBAL followed by Swern oxidation provided aldehyde 89. Reaction of 89 with the indicated Z-crotyl boronate according to Roush (See: Roush, W. R.; Hoong, L. K.; Palmer, M. A. J.; Straub, J. A.; Palkowitz, A. D. Asymmetric synthesis using tartrate modified allyl boronates. 2. Single and double asymmetric reactions with alkoxy-substituted aldehydes, *J. Org. Chem.* 1990, 55, 4117-4126) provided 90 in 63% isolated yield. PMB protection, ozonolysis and Wittig-Horner olefination then gave 91. This was converted to the E/Z diene 92 by DIBAL reduction, Dess-Martin oxidation, Still-Gennari olefination and desilylation with HF/pyridine.

[0092] Figure 19 shows the synthesis of two fragments with anti/anti configurations as assigned to dictyostatin 1 at C13-C15. Evan *anti*-aldol reaction of ent-4 and methacrolein (See: Evans, D. A.; Tedrow, J. S.; Shaw, J. T.; Downey, C. W. Diastereoselective magnesium halide-catalyzed *anti*-aldol reactions of chiral N-acyloxazolidinones. *J. Am. Chem. Soc.* 2002, 124, 392-393) followed by TFA treatment gave 93 in 78% yield. A minor diastereomer of 93 (about 16/1 ratio) was separated by chromatography. Silylation of 93 followed by hydroboration and oxidation provided alcohol 94 in 75% yield alongside the lactone resulting from cyclization of the terminal hydroxyl group with displacement of the chiral auxiliary (not shown, 10% yield). Silylation of 94 and reductive cleavage of the auxiliary provided 95, which was oxidized to 96 by the Swern method. Related aldehyde 98 was made by Roush allylboration of ent-17 (see 17 in Figure 3) with the indicated E-crotylborate (mismatched case, 4/1 selectivity) to give 97, followed by reaction with PMBBBr and ozonolysis.

After completion of the addition, the cooling bath was removed and the reaction mixture was allowed to warm to  $-20$  to  $-25$  °C for 30 min before being recooled to  $-78$  °C. Triisopropylborate (57.8 mL, 250 mmol) was added dropwise via cannula to the (*Z*)-crotylpotassium solution over 2 h. After addition, the reaction mixture was maintained at  $-78$  °C for 30 min and then rapidly poured into a 2L separatory funnel containing 470 mL of 1 N HCl saturated with NaCl. The aqueous layer was adjusted to pH 1 by using 1 N HCl (100-150 mL), and then a solution of (*R,R*)-diisopropyl tartrate (52.8 g, 250 mmol) in 88 mL of  $\text{Et}_2\text{O}$  was added. The phases were separated, and the aqueous layer was extracted with additional  $\text{Et}_2\text{O}$  (4 x 120 mL). [00216] (*R,R*)-Diisopropyl tartrate (E)-crotylboronate. An oven-dried 1L three-neck round bottom flask equipped with a magnetic stir bar and a -100 °C thermometer was charged with 206 mL of anhydrous THF and KOtBu (28.2 g, 250 mmol). This mixture was flushed with Ar and cooled to -78 °C, then trans-2-butene (23 mL, 250 mmol), condensed from a gas lecture bottle into a rubber-stoppered round bottom flask immersed in a -78 °C dry ice-acetone bath, was poured into the reaction mixture. *n*-BuLi (100 mL, 2.5 M in hexane) was then added dropwise via cannula over 1.5 h. After completion of the addition, the cooling bath was removed and the reaction mixture was allowed to warm to an internal temperature of -50 °C for 15 min then immediately re-cooled to -78 °C. Triisopropylborate (57.8 mL, 250 mmol) was added drop-wise via cannula to the (E)-crotylpotassium solution over 2 h. After addition, the reaction mixture was maintained at -78 °C for 30 min and then rapidly poured into a 2L separatory funnel containing 470 mL of 1 N HCl saturated with NaCl. The aqueous layer was adjusted to pH 1 by using 1 N HCl (100-150 mL), and then a solution of (*R,R*)-diisopropyl tartrate (52.8 g, 250 mmol) in 88 mL of Et<sub>2</sub>O was added. The

**[00217] Biology**

**[00218] General.** Tubulin without microtubule-associated proteins was prepared from fresh bovine brains.[32] The normoisotopic and tritiated forms of paclitaxel and normoisotopic docetaxel were provided by the Drug Synthesis and Chemistry Branch, National Cancer Institute. (+)-Discodermolide was from Novartis Pharmaceutical Corporation. Ca<sup>2+</sup>- and Mg<sup>2+</sup>-free RPMI-1640 culture medium were from GIBCO/BRL-Life Technologies. Fetal bovine serum (FBS) was from Hyclone. Cell lines were obtained from American Type Culture Collection (Manassas, VA).

**[00219] Tubulin Polymerization.**[32] Tubulin assembly was followed in a Beckman-Coulter 7400 spectrophotometer, equipped with an electronic Peltier temperature controller, reading absorbance (turbidity) at 350 nm. Reaction mixtures (0.25 mL final volume) contained tubulin (final concentration 10 µM; 1 mg/mL), monosodium glutamate (0.8 M from a stock solution adjusted to pH 6.6 with HCl), DMSO (final volume 4% v/v), and differing concentrations of test agent where indicated. Reaction mixtures without test agent were cooled to 0 °C and added to cuvettes held at 0.25-0.5 °C in the spectrophotometer. Test agent in DMSO was then rapidly mixed in the reaction mixture. Each run contained one positive control (paclitaxel, 10 µM final concentration) and one negative control (DMSO only). Baselines were established at 0.25-2.5 °C and temperature was rapidly raised to 30 °C (in approximately 1 min) and held there for 20 min. The temperature was then rapidly lowered back to 0.25-2.5 °C.

**[00220] Cell Growth Inhibition**[34] Cells were plated (500-2000 cells/well depending on the cell line) in 96-well microplates, allowed to attach and grow for 48 h, then treated with vehicle (4% DMSO, a concentration that allowed doubling times of 24 h or less) or test agent (50, 10, 2, 0.4 and 0.08 µM for the new agents; 0.001, 0.005, 0.010, 0.020 and 0.100 µM for paclitaxel and discodermolide) for the given times. One plate consisted of cells from each line used for a time zero cell number determination. The other plates in a given determination contained eight wells of control cells, eight wells of medium and each agent concentration tested in quadruplicate. Cell numbers were obtained spectrophotometrically (absorbance at 490 nm minus that at 630 nm) in a Dynamax plate reader after treatment with

3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium (MTS) using phenazine methanesulfonate as the electron acceptor. After initial screening with the above 5-fold dilutions, fifty percent growth inhibitory concentration (GI<sub>50</sub>) values were determined for each agent by repeating the screen using 2-fold dilutions (five concentrations) centered on the initial estimated GI<sub>50</sub> concentration, again in quadruplicate.

[00221] **Paclitaxel binding site inhibition assay.** [34] A stock solution of [<sup>3</sup>H]paclitaxel (26.8  $\mu$ M, 16.2 Ci/mmol), obtained from the NCI, was prepared in 37% (v/v) DMSO. The test agents were prepared in 25% (v/v) DMSO-0.75 M monosodium glutamate (prepared from a 2M stock solution adjusted to pH 6.6 with HCl). The radiolabeled paclitaxel and test agents, as indicated in terms of final concentrations, were mixed in equal volumes and warmed to 37 °C. A reaction mixture (50  $\mu$ L) containing 0.75 M monosodium glutamate, 4.0  $\mu$ M tubulin, and 40  $\mu$ M ddGTP (a non-hydrolyzable analog of GTP) was prepared and incubated at 37 °C for 30 min to preform microtubules. An equivalent volume of drug mixture with [<sup>3</sup>H]paclitaxel was added to preformed polymer and incubated for 30 min at 37 °C. Bound [<sup>3</sup>H]paclitaxel was separated from free drug by centrifugation of the reaction mixtures at 14000 rpm for 20 min at room temperature. Non-specific binding was determined by addition of a 12-fold excess of docetaxel. Radioactive counts from the supernatant (50  $\mu$ L) were determined by scintillation spectrometry. Bound [<sup>3</sup>H]paclitaxel was calculated from the following: total paclitaxel added to each reaction mixture minus the paclitaxel present in the supernatant (free drug). The % bound values were normalized to the control values with no inhibitor added.
